

Practice questions

1. A point is chosen uniformly at random inside a triangle with base 1 and height 1. Let X be the distance from the point to the base of the triangle. Find the CDF and the PDF of X . (*Textbook problem 3.2.5*)

Solution: The PDF of the point is uniform over the triangle which has area $1/2$, so it has value 2 inside the triangle and zero outside. The event $X > x$ consists of all the points in the triangle that are at distance more than x from the base, which is itself a triangle of base and height $1 - x$. Therefore $P(X > x) = 2(1 - x)^2/2 = (1 - x)^2$. The CDF is $P(X \leq x) = 1 - (1 - x)^2 = 2x - x^2$ and the PDF is $f_X(x) = dP(X \leq x)/dx = 2(1 - x)$.

2. The arrival times of the 193 ENGG 2430A / ESTR 2004 to class are normal random variables with a mean value of 9.25am and a standard deviation of 5 minutes.
 - (a) What is the expected number of students that have arrived by 9.30am?
 - (b) Assuming students' arrivals are independent, what is the probability that everyone has made it by 9.45am?

Solution: For the CDF calculations I used the Python function `scipy.stats.norm.cdf`, which outputs the value of the CDF of a normal random variable.

- (a) Let N be a $\text{Normal}(0, 1)$ random variable. The delay of each student in minutes is modeled by $5N$. The probability that any given student has arrived by 9.30am is the probability that N is at most 1 which is about 84.13%. By linearity of expectation, the expected number of students that make it in time for class is about $84.13 \cdot 193 \approx 162$.
 - (b) The probability that any given student hasn't made it by 9.45 is $P(N > 4) = 1 - P(N < -4) \approx 1 - 3.167 \cdot 10^{-5}$, so the probability that all the students have made it by 9.45 is $P(N > 4)^{193}$, which is about 99.3%.
3. Three points are dropped at random on the perimeter of a circle with 1 unit circumference.
 - (a) What is the probability that they all fall within $1/4$ of a unit of one another?
 - (b) What is the probability that every pair of them is at least $1/4$ of a unit apart?
(**Hint:** Fix one of the three points.)

Solution: Let's call the three points a , b , and c . By symmetry, we can position a on the circle in an arbitrary way. Let X and Z be the positions of b and c relative to a clockwise along the circle. We model X and Y as independent $\text{Uniform}(0, 1)$ random variables.

- (a) The event E is the intersection of events A , B , C described by the predicates: (1) $x \in [0, 1/4] \cup [3/4, 1]$ (b is close to a); (2) $y \in [0, 1/4] \cup [3/4, 1]$ (c is close to a); and (3) $|x - y| \in [0, 1/4] \cup [3/4, 1]$ (b is close to c , clockwise or counterclockwise). $A \cap B \cap C$ is the shaded set in the following diagram and has probability $3/16$.

- (b) The event E' of interest is now $A' \cap B' \cap C'$, where A', B', C' are the sets (1) $x \in [1/4, 3/4]$ (b is far from a); (2) $y \in [1/4, 3/4]$ (c is far from a); and (3) $|x - y| \in [1/4, 3/4]$ (b is far from c). This is represented by the shaded region below and has area $1/16$.

Another way to solve part (b) (or to check your answer) is via the axioms of probability. The complement of E' equals $A \cup B \cup C$ (some pair of points is close), so by inclusion-exclusion:

$$\begin{aligned} P(E'^c) &= P(A \cup B \cup C) \\ &= P(A) + P(B) + P(C) - P(A \cap B) - P(B \cap C) - P(C \cap A) + P(A \cap B \cap C). \end{aligned}$$

Here, A is the event that points a and b are less than $1/4$ of an inch apart, so $P(A) = 1/2$. For the same reason $P(B) = P(C) = 1/2$. The events A, B are independent so $P(A \cap B) = P(A)P(B) = 1/4$. For the same reason $P(B \cap C) = P(C \cap A) = 1/4$. In part (a) we calculated that $P(A \cap B \cap C) = 3/16$, so

$$P(E'^c) = 3 \times \frac{1}{2} - 3 \times \frac{1}{4} + \frac{3}{16} = \frac{15}{16}$$

and $P(E') = 1/16$.

4. A coin has probability P of being heads, where P itself is a $\text{Uniform}(0, 1)$ random variable. The coin is flipped twice. Given that it comes out heads both times, what is the (posterior) PDF of P ? What is its expected value?

Solution: Let X be the number of heads. By Bayes' rule,

$$f_{P|X}(p|x) = \frac{f_{X|P}(x|p)f_P(p)}{f_X(x)},$$

where $f_{P|X}(\cdot|x)$ is the conditional PDF of P given x heads were observed, $f_{X|P}(x|p) = p^x(1-p)^{2-x}$ is the conditional PMF of X given the coin has bias p , $f_P(p)$ is the (prior) PDF of the Uniform(0, 1) random variable P , and f_X is the PMF of X . Plugging in these formulas, we get that

$$f_{P|X}(p|2) = \frac{p^2 \cdot 1}{f_X(x)} = \frac{p^2}{f_X(x)},$$

when $0 \leq p \leq 1$. Since $f_{P|X}(p|2)$ is a PDF it must integrate to one, so

$$f_X(x) = \int_0^1 p^2 dp = \frac{1}{3}$$

and so $f_{P|X}(p|2) = 3p^2$. The expected value of P given $X = 2$ is

$$E[P|X = 2] = \int_0^1 p \cdot f_{P|X}(p|2) dp = \int_0^1 3p^3 dp = \frac{3}{4}.$$

5. Here is a way to solve Buffon's needle problem without calculus. Recall that an ℓ inch needle is dropped at random onto a lined sheet, where the lines are one inch apart.

- Let A be the number of lines that the needle hits. Let B be the number of times that a polygon of perimeter ℓ hits a line. Show that $E[A] = E[B]$. (**Hint:** Use linearity of expectation.)
- Assume that $\ell < \pi$. Calculate the expected number of times that a circle of perimeter ℓ hits a line.
- Assume that $\ell < 1$. Use part (a) and (b) to derive a formula for the probability that the needle hits a line. (**Hint:** The number of hits is a Bernoulli random variable.)

Solution:

- Suppose the polygon has n edges of length a_1, a_2, \dots, a_n . Break up the needle into segments of lengths a_1, a_2, \dots, a_n . Let A_i and B_i be the number of lines hit by the i -th segment of the needle and the i -th edge of the polygon, respectively. Then

$$A = A_1 + \dots + A_n \quad \text{and} \quad B = B_1 + \dots + B_n.$$

By linearity of expectation

$$E[A] = E[A_1] + \dots + E[A_n] \quad \text{and} \quad E[B] = E[B_1] + \dots + E[B_n].$$

Since the i -th edge of the polygon and the i -th segment of the needle are identical, $E[A_i] = E[B_i]$. It follows that $E[A] = E[B]$.

- Let C be the number of times a circle intersects a line. We calculate the p.m.f. of C . Let d be the line segment representing the diameter of the circle that is perpendicular to the lines on the sheet. Since $\ell < \pi$, the length of d is less than 1. The circle hits a line twice if d crosses a line, once if d touches one of the lines, and zero times if d does not intersect any of the lines. The probability that d crosses a line is exactly the length of d , namely ℓ/π , and the probability that d touches a line is zero. Summarizing, the p.m.f. of C is

$$\begin{array}{c|ccc} c & 0 & 1 & 2 \\ \hline P(C=c) & 1 - \ell/\pi & 0 & \ell/\pi \end{array}$$

Therefore $E[C] = 2\ell/\pi$.

- If we view the circle as a polygon with infinitely many sides, putting together part (a) and (b) we get that $E[A] = E[C] = 2\ell/\pi$. Since $\ell < 1$, the number of times the needle intersects a line is a 0/1 valued random variable, so $E[A] = P(A = 1) = P(\text{the needle hits a line})$. Therefore the probability the needle hits a line is exactly $2\ell/\pi$.
